Design provisions for torsion in reinforced concrete members have been developed and included in the ACI 318-71 Building Code. These provisions are not applicable to prestressed concrete. Based on a thorough review of available research data on torsion in prestressed concrete, this paper proposes an extension of the ACI design procedures to cover torsion in prestressed concrete. The basic approach consists of determining the concrete contribution to the ultimate strength of a member and then proportioning reinforcement for the remaining portion of the required ultimate strength. Formulas for the nominal torsional stress and the basic equation for torsional strength of reinforced members are presented, and followed by a discussion of the torsion-shear interaction relation, taking into account the effect of the prestressing force. The requirements for both web and longitudinal reinforcements for torsion are explained. The proposed procedures are illustrated by a design example of a precast prestressed L-girder in a roof framing subjected to combined torsion, bending, and shear. It is believed that the proposed procedure is reasonably conservative and future refinements and simplifications are possible when more complete research data become available.
The problem of torsion in concrete structures has received considerable attention of design engineers in recent years. In 1971, the ACI Building Code (ACI 318-71)\(^1\) included for the first time explicit requirements of torsion design for reinforced concrete developed on the basis of substantial research data. However, the code provisions are not applicable to prestressed concrete members, for which research has been in progress but design criteria have yet to be developed.

This paper presents a proposed design procedure for torsion in prestressed concrete, based on a thorough analysis of 394 test results available in the literature.\(^2\) The proposal is in close parallel with the ACI Code procedure for reinforced concrete.

The basic approach consists of determining the concrete contribution to the ultimate strength of a member and then proportioning reinforcement for the remaining portion of the required ultimate strength. It is believed that the proposed procedure is reasonably conservative and future refinements and simplifications are possible when more complete research data become available.

In developing the proposed procedure, the authors have benefited from helpful discussions with several members of the ACI Committee 438 on Torsion. However, this proposal should not be regarded as a committee-endorsed document.

In the following discussion, the usual capacity reduction factor \(\phi\) is not included for the sake of convenience.

\section*{TORSIONAL SHEAR STRESS}

\subsection*{Rectangular section}

A prestressed concrete member without web reinforcement fails, under torsion, in the form of skew bending. The torsional stress of a rectangular section can be expressed by:

\[ \tau_u = \frac{T_u}{\alpha x^2 y} \]  \hspace{1cm} (1)

where

\begin{align*}
x &= \text{shorter side of rectangular section} \\
y &= \text{longer side of rectangular section} \\
\alpha &= \text{torsion coefficient}
\end{align*}

It will be recalled that Eq. (1) is of the basic form for either the elastic the-
ory, the plastic theory or the skew bending theory of torsion. The coefficient $\alpha$ varies from 0.208 to $\frac{3}{4}$ in the elastic theory and from $\frac{1}{2}$ to $\frac{3}{4}$ in the plastic theory. For simplicity, the ACI Code adopted a value of $\frac{1}{3}$ in accordance with the skew bending theory.\(^3\)

Hsu\(^4\) has shown that the torsional capacity of a prestressed section without reinforcement, or the cracking torque of a prestressed section with reinforcement is reached when:

$$\tau_u = (0.85 f_p) \sqrt{1 + \frac{10 \sigma / f'_c}{f'_c}}$$  \hspace{1cm} (2)

where

- $f_p$ = modulus of rupture
- $\sigma$ = average prestress on section

The factor $(0.85 f_p)$ is nearly equal to the tensile strength of concrete $f'_c$ and may be taken as $6\sqrt{f'_c}$. Hence, combining Eqs. (1) and (2):

$$\tau_u = 6\sqrt{f'_c} \sqrt{1 + \frac{10 \sigma / f'_c}{f'_c}} = \frac{T_u}{\alpha \pi x^2 y}$$

or

$$\alpha = \frac{T_u}{x^2 y 6\sqrt{f'_c} \sqrt{1 + 10 \sigma / f'_c}}$$  \hspace{1cm} (3)

---

**Fig. 1. Variation of torsion coefficients with aspect ratio.**
Using the test results of 218 concentrically or eccentrically prestressed rectangular beams, the value of $\alpha$ has been computed for each beam by Eq. (3) and these values are plotted against the aspect ratio $y/x$ in Fig. 1. Also plotted for comparison in Fig. 1 are the curves for the elastic and plastic torsion coefficients as well as the value currently specified by the ACI Code.

It can be seen that for sections of low aspect ratio, the ACI 318-71 value of $1/3$ could be quite unconservative. Since, as will be shown later, the contribution of the concrete to the ultimate torsional strength is a much larger portion of the cracking strength for prestressed members than for non-prestressed members, it is prudent and essential that the nominal torsional stress be evaluated more accurately. Therefore, it is proposed that the coefficient $\alpha$ in Eq. (1) be taken as:

$$\alpha = \frac{0.35}{0.75 + \frac{x}{y}}$$

(4)

which represents a reasonably conservative lower bound to the experimental data.

---

*Computed from Equation (1) multiplied by 4h/x.

Flanged section

For a flanged section, the same assumption implied by ACI 318-71 will be used. That is, the torsional strength of a flanged section can be expressed as the sum of the strengths of the individual components. Hence:

$$\tau_u = \frac{T_u}{\sum \alpha x^2 y} \quad (5)$$

Eq. (5) is identical to the ACI 318-71 Eq. (11-16) except for the modification of torsional coefficient \(\alpha\) as expressed by Eq. (4). The section may be divided into component rectangles such that the quantity \(\sum \alpha x^2 y\) would be a maximum.

Comparison of Eq. (5) with test results reported in the literature indicates that the method is reasonably safe as shown in Table 1. However, it should be cautioned that only two investigations\(^5,6\) have been reported, consisting of 24 test specimens, all being somewhat stocky in cross section. The margin of safety seems to reduce as the cross section becomes more stocky such as the specimens tested by Zia. For such disproportionate sections, it would seem logical to disregard the small outstanding flanges.

Box section

Based on test results, ACI 318-71 specifies that for reinforced concrete box sections with a wall thickness \(h\) not less than \(x/4\), where \(x\) is the overall width of the box section, the torsional strength of the box section may be taken as that of a comparable solid rectangular section with the same overall dimension.

If the wall thickness \(h\) is less than \(x/4\) but greater than \(x/10\), the torsional strength of the box section is reduced and the strength reduction is accounted for by a reduction factor \(4h/x\) multiplied to the denominator on the right-hand side of Eq. (1).

This design approach seems also applicable to prestressed concrete box sections. Although only four tests of prestressed concrete box sections under pure torsion have been reported in the literature that can be used for comparison, application of the ACI design rule for these test results indicates a considerable margin of safety in all cases as shown in Table 2.

For box sections with a very thin wall, \(h\) approaching \(x/10\), caution should be exercised against possible
wall buckling or crushing, particularly when high prestress is applied.

---

**BASIC EQUATION FOR TORSIONAL STRENGTH**

The basic equation for torsional strength has been developed from the test results of prestressed beams under pure torsion. Tests conducted by Hsu show that the ultimate torsional strength can be expressed as the sum of the strength contributed by the concrete and the strength contributed by the web reinforcement, for both prestressed and non-prestressed beams (see Fig. 2). The effect of prestress is to increase the contribution of the concrete to the ultimate torsional strength, while the contribution of the reinforcement remains unchanged.

Referring to Fig. 3, it can be seen that for non-prestressed beams the contribution by concrete $T_o$ is only a portion of the torsional strength $T_{up}$ of a corresponding plain concrete section. Likewise, for prestressed beams, the contribution by concrete $T_o'$ is also a portion, but a greater portion, of the torsional strength of a corresponding prestressed concrete section without web reinforcement. Accordingly, the basic strength equation for prestressed
Fig. 3. Relation between ultimate torque for prestressed and non prestressed reinforced, rectangular beams (after Hsu).

beams can be expressed as:

$$T_u = T_o' + \frac{\Omega x_1 y_1 A_\text{fsy}}{s}$$

and

$$\Omega = 0.66 \, m + 0.33 \, y_1/x_1$$

where

- $T_o' = \text{strength contributed by concrete}$
- $x_1 = \text{shorter leg of a closed stirrup}$
- $y_1 = \text{long leg of a closed stirrup}$
- $A_\text{s} = \text{cross-sectional area of one leg of a stirrup}$
- $f_{\text{fsy}} = \text{yield strength of stirrup}$
- $s = \text{spacing of stirrup}$
- $m = \text{volume ratio of longitudinal reinforcement to web reinforcement}$

If the yield strength of the longitudinal reinforcement is different from that of the web reinforcement, then the parameter $m$ should be replaced by $m_{f_{\text{sy}}/f_{\text{fsy}}}$ in which $f_{\text{sy}}$ is the yield strength of the longitudinal reinforcement. Hsu has recommended that:

$$0.7 \leq m_{f_{\text{sy}}/f_{\text{fsy}}} \leq 1.5$$

and

$$y_1/x_1 \leq 2.6$$

In Fig. 3, the cracking (or ultimate) torque of a plain concrete member can be obtained by substituting $6\sqrt{f_c'}$ for $T_u$ in Eq. (1). Thus:

$$T_{up} = (\alpha x_1 y_1)6 \sqrt{f_c'}$$

The ordinate $T_o$ has been determined by Hsu experimentally as:

$$T_o = 0.4 \left(\frac{1}{3} \frac{x_1^2 y_1}{s}\right)6 \sqrt{f_c'}$$

$$= 0.133(x_1^2 y_1)6 \sqrt{f_c'}$$

Hence:

$$T_o' = T_{up} \sqrt{1 + 10 \sigma/f_c' - (T_{up} - T_o)}$$

$$= T_{up} \left[\sqrt{1 + 10 \sigma/f_c' - (1 - T_o/T_{up})}\right]$$

$$= (\alpha x_1 y_1)6 \sqrt{f_c'} \left(\sqrt{1 + 10 \sigma/f_c' - k}\right)$$

where

$$k = 1 - T_o/T_{up} = 1 - 0.133/\alpha$$

Thus, by combining Eqs. (6) and (10), the basic strength equation becomes:

$$T_u = (\alpha x_1 y_1)6 \sqrt{f_c'} \left(\sqrt{1 + 10 \sigma/f_c' - k}\right) + \frac{\Omega x_1 y_1 A_\text{fsy}}{s}$$

Likewise, for a box section:

$$T_u = \frac{4h}{x} \left[(\alpha x_1 y_1)6 \sqrt{f_c'} \times \left(\sqrt{1 + 10 \sigma/f_c' - k}\right) + \frac{\Omega x_1 y_1 A_\text{fsy}}{s}\right]$$

and, for a flanged section:

$$T_u = (\alpha x_1 y_1)6 \sqrt{f_c'} \times \left(\sqrt{1 + 10 \sigma/f_c' - k}\right) + \frac{\Omega x_1 y_1 A_\text{fsy}}{s}$$

in which the value of $k$ is determined

*Computed from Equation (12)

on the basis of the largest component rectangle where the web reinforcement is usually placed.

By comparison with available test results, it has been shown that, with only a few exceptions, the above three equations are reasonably and consistently on the safe side (see Tables 3 through 5). It would appear, therefore, that these equations are acceptable as the basis of design.

TORSION-SHEAR INTERACTION

Tests have shown that the interactions between torsion and shear for prestressed beams without web reinforcement can be adequately represented by a circular curve. By following the same development adopted by ACI 318-71, it can be shown that the permissible shear stress for torsion and shear are, respectively:
Table 4. Comparison of experimental ultimate torque of eccentrically prestressed rectangular beams with Eq. (12).

*Computed from Equation (12).

$$\tau_c = \frac{\tau'_c}{\sqrt{1 + \left[\frac{v_u}{\beta \tau_u}\right]^2}}$$  \hspace{2cm} (15)

where

$$\tau'_c = 6\sqrt{\tau'_c} (1 + \frac{10 \sigma_{ep}}{f'_c} - k)$$  \hspace{2cm} (17)

$$v'_c = \text{lesser of } v_{ct} \text{ and } v_{we} \text{ as defined by ACI Eqs. (11-11) and 11-12, respectively.}$$

$$v_c = \frac{v'_c}{\sqrt{1 + \left(\frac{\beta \tau_u}{v_u}\right)^2}}$$  \hspace{2cm} (16)

$$\beta \approx \frac{1}{2} \left(\frac{v'_c}{\tau'_c}\right)$$  \hspace{2cm} (18)
It is noted that \( r_s' \) and \( v_o' \) in Eqs. (15) and (16) are the permissible shear stresses for torsion and flexural shear, respectively, if torsion or shear is acting alone. The factor in the denominator of these equations accounts for the interaction between torsion and shear. For a discussion of Eq. (18), see Reference 2.

WEB REINFORCEMENT FOR TORSION

Recasting the basic equation for torsional strength discussed above and taking into account the torsion-shear interaction, we have:

\[
T_u = \Sigma \alpha x^2 y \tau _0 + \frac{\Omega x^2 y A_{ts} y}{s} \\
= \Sigma \alpha x^2 y \tau _u
\]

Transposing terms:

\[
\Sigma \alpha x^2 y (\tau _u - \tau _0) = \frac{\Omega x^2 y A_{ts}}{s}
\]

or

\[
A_t = \frac{(\tau _u - \tau _0) s \Sigma \alpha x^2 y}{\Omega x^2 y A_{ts}}
\]

in which, for simplicity, the coefficient \( \Omega \) may be taken as:

\[\Omega = 0.66 + 0.33 \frac{y_1}{x_1}\]

Table 5. Comparison of experimental ultimate torque of flanged and box sections with Eq. (14) and Eq. (13), respectively.

</table>

*Computed from Equation (14) or Equation (13).
Thus, the web reinforcement is required for the torsional shear stress in excess of that carried by the concrete. The web reinforcement for torsion must be in the form of closed stirrups and it should be added to the web reinforcement for flexural shear. Note that the latter could be open stirrups.

**MINIMUM AND MAXIMUM WEB REINFORCEMENT**

To avoid brittle failure, a minimum amount of web reinforcement must be provided to resist both torsion and shear. A series of tests with prestressed rectangular beams, containing a minimum amount of web reinforcement as specified by ACI 318-71 for shear, have shown that the post-cracking ductility of the beams was insufficient under high ratios of torsion and shear. In view of the sudden and explosive nature of the torsional failure, and the lack of sufficient research data, it is suggested that a beam should be reinforced for no less than its cracking torque.

At the other extreme, considerations should be given to the possible danger of over-reinforcing a member such that a compressive failure of the concrete might occur before the reinforcement yields. To avoid this type of failure, an upper limit of web reinforcement should be established by specifying a maximum permissible nominal torsional stress. If the design stress exceeds this limit, then a larger beam section would have to be used.

Since the prestressing force exerts a compressive load on a member before it is subjected to torque, it seems logical that the upper limit on the nominal torsional stress should be a function of the prestress ratio \( \sigma/f'_c \). Based on this reasoning, it will be assumed that the maximum torque a rectangular section can carry is:

\[
T_{u(\text{max})} = \alpha x^2 y C \sqrt{f'_c} \sqrt{1 + 10 \sigma/f'_c} \tag{20}
\]

in which \( C \) is an unknown coefficient yet to be determined. It is assumed that \( C \) is a function of \( \sigma/f'_c \).

For the extreme case of \( \sigma/f'_c = 0 \), i.e., reinforced concrete members without prestress, ACI 318-71 specifies 12 \( \sqrt{f'_c} \) as the limiting stress. Thus:

\[
T_{u(\text{max})} = \frac{1}{3} x^2 y 12 \sqrt{f'_c} = \alpha x^2 y C \sqrt{f'_c}
\]

or \( C = 4/\alpha \).

For a typical cross section with an aspect ratio of two:

\[
\alpha = \frac{0.35}{0.75 + 0.5} = \frac{0.35}{1.25} = 0.28
\]

and

\[
C = 4/0.28 \approx 14
\]

Hence, in Eq. (20), the coefficient \( C \) can be taken as 14 for \( \sigma/f'_c = 0 \).

For members subjected to high values of \( \sigma/f'_c \), Zia\(^9\) has shown that a transition from tension failure to compression failure would take place at \( \sigma/f'_c \approx 0.6 \). Since the tensile strength of the concrete can be taken as \( 6\sqrt{f'_c} \), it is then reasonable to limit the maximum nominal torsional stress as \( 6\sqrt{f'_c} \) for \( \sigma/f'_c = 0.6 \). Assuming a linear function of \( \sigma/f'_c \) between these two limiting values for \( C \), one obtains:

\[
C = 14 - 13.33 (\sigma/f'_c) \tag{21}
\]

In Fig. 4, test results are compared with Eq. (21) and it is noted that, with a few exceptions, all the data representing tension failure fall below the curve of Eq. (21) and the data for those beams reported to have failed in compression fall above the curve. It would seem that the coefficient \( C \) as represented by Eq. (21) is a very reasonable value to be used as the upper limit of the nominal shear stress for both rectangular and flanged sections.

Eq. (20) can be extended to the case of combined torsion and shear, again
Fig. 4. Comparison of Eq. (21) with tests results for upper limit of nominal torsion stress.

Based on the circular interaction relation. Thus:

\[
\tau_{u(\text{max})} = \frac{C' \sqrt{f_c'}}{\sqrt{1 + \left[ \left( \frac{C'}{10} \right) \left( \frac{\nu_u}{\tau_u} \right) \right]^2}} \quad (22)
\]

\[
v_{u(\text{max})} = \frac{10 \sqrt{f_c'}}{\sqrt{1 + \left[ \left( \frac{10}{C'} \right) \left( \frac{\tau_u}{\nu_u} \right) \right]^2}} \quad (23)
\]

where

\[
C' = C \sqrt{1 + 10 \frac{\sigma/f_c'}{f_c'}}
\]

\[
C = 14 - 13.33 \left( \frac{\sigma/f_c'}{f_c'} \right)
\]

The term \(10 \sqrt{f_c'}\) in Eq. (23) is based on the ACI Code upper limit for flexural shear stress and is obtained by taking \(v_c = 2 \sqrt{f_c'}\) in Section 11.6.4 of ACI 318-71.
LONGITUDINAL TORSION REINFORCEMENT

To resist the longitudinal component of the diagonal tension induced by torsion, longitudinal reinforcement must be provided in addition to that required by flexure. This longitudinal reinforcement should be approximately of equal volume as that of stirrups for torsion in order that both will yield at failure, i.e., \( m f_{iy}/f_{sy} = 1 \). Therefore:

\[
A_l = \frac{2A_t(x_1 + y_1)}{s} \left( \frac{f_{sy}}{f_{iy}} \right)
\]

(24)

\( A_l \) is the total area of longitudinal torsion reinforcement and must be distributed around the inside perimeter of the closed stirrups.

The question of whether the pre-stressing steel can be considered as a part of longitudinal torsion reinforcement should be considered. The pre-stressing steel is provided primarily for resisting flexure and often is not effectively distributed around the perimeter of the closed stirrups.

Tests\(^2\) have shown that without additional longitudinal reinforcement of mild steel, prestressed beams would fail abruptly under high torsion. In light of this observation, it is recommended that until more research data become available, only the pre-stressing steel in excess of that required for flexure and located around the perimeter of closed stirrups should be considered as a part of the longitudinal torsion steel, having an equivalent area of:

\[
A_{p(tld)} \text{eq} = A_{ps(eff)} f_{ps(eff)}/f_{iy}
\]

in which \( A_{ps(eff)} \) is the excess area of prestressing steel and \( f_{ps(eff)} \) is the effective stress in prestressing steel.

OTHER LIMITATIONS

To ensure the development of ultimate torsional strength and to control cracking and stiffness at service load, the maximum yield strength of reinforcement should be limited to 60,000 psi and the maximum spacing of stirrups should not exceed \((x_1 + y_1)/4\) nor 12 in. If required, longitudinal torsion reinforcement of not less than a No. 3 bar should be distributed around the stirrup at no more than 12 in. apart. In any event, at least one No. 3 bar should be placed at each corner of the stirrup.

For reinforced concrete members, ACI 318-71 permits the torsional effect to be neglected if the torsional shear stress is less than 25 percent of the cracking stress. This same requirement would seem justified for prestressed beams. That is to say, the torsional effect may be neglected in design if the torsional stress \( \tau_u \) is less than:

\[
1.5 \sqrt{f_{c'}} \left( \sqrt{1 + \frac{10 \sigma}{f_{c'}}} \right)
\]

SUMMARY OF PROPOSED DESIGN PROCEDURE

The design procedure proposed here-in may be summarized as follows:

1. Determine the nominal torsional stress according to Eq. (5). The stress \( \tau_u \) should not exceed that specified in Eq. (22).

2. If \( \tau_u < 1.5 \sqrt{f_{c'}} \left( \sqrt{1 + \frac{10 \sigma}{f_{c'}}} \right) \), torsion may be neglected.

3. If \( \tau_u > \tau_c \) according to Eq. (15), determine the required web reinforcement from Eq. (19). Check the minimum web reinforcement requirement.

4. Determine the required longitudinal torsion reinforcement according to Eq. (24). Check the minimum requirement.

DESIGN EXAMPLE

To illustrate the above design procedure, let us consider the design of torsional reinforcement in a prestressed...
concrete L-girder in a roof framing similar to that given in the PCA Design Notes as shown in Fig. 5. The design live load plus insulation and roofing is 40 psf. For this loading, a double tee 8DT18A and a L-girder 18LB30 can be chosen according to the PCI Design Handbook.

From an analysis for flexure, thirteen 1/2-in. diameter 7-wire strands (270 ksi grade) are required for the L-girder with the eccentricity of prestress at midspan being 7.3 in. and that at the support being 3.65 in. Assume that the loss of prestress is 22 percent; $f'_c = 5000$ psi; $f_{ct} = 3500$ psi; $f_y = f_{ty} = 40$ ksi. In the following calculations, the usual capacity reduction factor for shear and torsion $\phi = 0.85$ will be applied.

(a) Calculate $T_u$ and $V_u$ for spandrel

\[ W_{DL} = 30' \times 0.062 = 1.85 \text{ kips per ft (double tees)} \]
\[ 0.45 \text{ kips per ft (spandrel beam)} \]
\[ 2.30 \text{ kips per ft} \]
\[ W_{LL} = 0.040 \times 30' = 1.20 \text{ kips per ft} \]
Assume no continuity at columns.

\[ DL = 1.4 \times 2.30 \times 30 \times \frac{1}{2} = 48.3 \text{ kips} \]
\[ LL = 1.7 \times 1.20 \times 30 \times \frac{1}{2} = 30.6 \text{ kips} \]

$V_u$ at centerline of support $= 78.9 \text{ kips}$
Neglecting restraints from double tees and walls.
\[ DL = 1.4 \times 1.85 \times (9/12) \times 15' = 29.1 \text{ ft-kips} \]
\[ LL = 1.7 \times 1.20 \times (9/12) \times 15' = 22.9 \text{ ft-kips} \]
\[ T_u \text{ at centerline of support} = 52.0 \text{ ft-kips (or 625 in.-kips)} \]

(b) Calculate shear stress \( v_u \)
\[ V_u \text{ at } "d = 22.7 \text{ in.}" \text{ from support} = 78.9 \times 13/15 = 68.4 \text{ kips} \]
\[ v_u = V_u/\phi b_w d = 68,400/0.85 \times 12 \times 22.7 = 295 \text{ psi} \]

(c) Calculate torsion stress \( \tau_u \) with Eq. (5)
\[ \tau_u = T_u/\phi(\Sigma \alpha x^2 y) \]
For maximum \( \Sigma \alpha x^2 y \), consider beam web and outstanding ledge as component rectangles.
\[ \alpha_1 = \frac{0.35}{0.75 + 12/30} = 0.304 \text{ (beam web)} \]
\[ \alpha_2 = \frac{0.35}{0.75 + 6/12} = 0.280 \text{ (ledge)} \]
\[ \Sigma \alpha x^2 y = 0.304 \times 12^2 \times 30 + 0.280 \times 6^2 \times 12 = 1313 + 121 = 1434 \text{ in.}^3 \]
\[ T_u \text{ at } "d" \text{ from face of support} = 625 \times 13/15 = 541 \text{ in.-kips} \]
\[ \tau_u = 541/0.85 \times 1434 = 445 \text{ psi} \]
Effective prestress = 0.78 \times 189 = 147 ksi
\[ \sigma = 13 \times 0.153 \times 147/432 = 0.677 \text{ ksi = 677 psi} \]
\[ \sigma/f_o' = 677/5000 = 0.135 \]
1.5 \( \sqrt{f_o'^2 + 10 \sigma/f_o'} \times 1.5 \times 70.5 \times 1.53 = 162 \text{ psi < 677 psi} \]
Requires torsion design.

(d) Check \( \tau_u(\text{max.}) \) and \( v_u(\text{max.}) \) with Eqs. (22) and (23)
\[ C = 14 - 13.33(\sigma/f_o') = 14 - 13.33(0.135) = 12.2 \]
\[ C' = C\sqrt{1 + 10 \sigma/f_o'} = 12.2 \times 1.53 = 18.7 \]
\[ \tau_u(\text{max.}) = \frac{C' \sqrt{f_o'}}{\sqrt{1 + \left( \frac{C'}{10} \cdot \frac{\tau_u}{\tau_u} \right)^2}} = \frac{18.7\sqrt{5000}}{\sqrt{1 + \left( \frac{18.7}{10} \cdot \frac{295}{445} \right)^2}} \]
\[ = 1322/\sqrt{2.54} = 832 \text{ psi > } \tau_u \text{ (ok)} \]
\[ v_u(\text{max.}) = \frac{10 \sqrt{f_c'}}{\sqrt{1 + \left( \frac{10}{C'} \cdot \frac{\tau_u}{\tau_u} \right)^2}} = \frac{10\sqrt{5000}}{\sqrt{1 + \left( \frac{10}{18.7} \cdot \frac{445}{295} \right)^2}} \]
\[ = 707/\sqrt{1.65} = 550 \text{ psi > } v_u \text{ (ok)} \]
Section is adequate for torsion and shear.

(e) Calculate torsion stress and shear stress carried by concrete \( \tau_c \) and \( v_c \) with Eqs. (15) and (16)
\[ \tau_c = 6\sqrt{f_c'} \left( \sqrt{1 + 10 \sigma/f_c'} - k_{\text{web}} \right) \]
\[ k_{\text{web}} = 1 - 0.133/\alpha_1 = 1 - 0.133/0.304 = 0.563 \]
\[ \tau_c = 6\sqrt{5000} \left( \sqrt{1 + 10(0.135)} - 0.563 \right) = 412 \text{ psi} \]
\( v' = \text{lesser of } v_{ci} \text{ and } v_{cc} \text{ from ACI Eqs. (11-11) and (11-12)} \)

\[
v_{cc} = 3.5 \sqrt{f_{c}' + 0.3 f_{pc} + \frac{V_p}{B_w d}}
\]

\[
= 3.5 \sqrt{5000 + 0.3(677) + 5930/12 \times 22.7}
\]

\[
= 247 + 203 + 22 = 472 \text{ psi}
\]

\[
\beta = \frac{1}{2} \left( \frac{v'}{\tau_c} \right) = \frac{1}{2} \left( \frac{472}{412} \right) = 0.573
\]

\[
\tau_c = \frac{\tau_c'}{\sqrt{1 + \left( \frac{1}{\beta} \cdot \frac{v_u}{\tau_u} \right)^2}} = \frac{412}{\sqrt{2.34}} = 270 \text{ psi}
\]

\[
v_c = \frac{v_c'}{\sqrt{1 + \left( \frac{\beta \tau_u}{v_u} \right)^2}} = \frac{472}{\sqrt{1 + \left( \frac{0.573 \cdot 445}{295} \right)^2}}
\]

\[
= \frac{472}{\sqrt{1.75}} = 358 \text{ psi}
\]

(f) Calculate web reinforcement for torsion with Eq. (19)

\[
x_1 = 12 - 2 \times 1.5 = 9 \text{ in.}
\]

\[
y_1 = 30 - 2 \times 1.5 = 27 \text{ in.}
\]

\[
\Omega = 0.66 + 0.33 (y_1/x_1)
\]

\[
= 0.66 + 0.33 (27/9) = 1.65 > 1.5
\]

Use \( \Omega = 1.5 \)

\[
A_t = \frac{(\tau_u - \tau_c) s \Sigma a x^2 y}{\Omega x_1 y_1 f_{sy}}
\]

\[
A_t = \frac{(445 - 270) \times 1434}{1.5 \times 9 \times 27 \times 40,000} = 0.0173 \text{ sq in. per in.}
\]

Maximum \( s = x_1 + y_1 = \frac{9 + 27}{4} = 9 \text{ in.} < 12 \text{ in.} \)

\[
A_t = 0.0173 \times 9 = 0.155 \text{ sq in.}
\]

Use No. 4 closed stirrups at 9 in. on center

(g) Check minimum web reinforcement for torsion

Minimum web reinforcement should be what is required to develop cracking torque of section.

Torsional stress at cracking:

\[
\tau_{cr} = 6 \sqrt{f_{c}'} \sqrt{1 + 10 \sigma/f_{c}'}
\]

\[
= 6 \sqrt{5000} \sqrt{1 + 10(0.135)} = 650 \text{ psi}
\]

Torsional stress carried by concrete under pure torsion is \( \tau_c' = 412 \text{ psi} \).

\[
A_t = \frac{(650 - 412) \times 1434}{1.5 \times 9 \times 27 \times 40,000} = 0.0234 \text{ sq in. per in.}
\]

\[
A_t = 0.0234 \times 9 = 0.21 \text{ sq in.} \approx 0.20 \text{ sq in.}
\]

Thus, No. 4 closed stirrups at 9 in. on center is adequate.
(h) Calculate web reinforcement for shear

\[ v_u = 295 \text{ psi} \]
\[ v_c = 358 \text{ psi} > v_u \]

But \( v_u > v_c/2 \); so minimum web reinforcement is required.

\[ A_w = \frac{50b_{ws}}{f_{sv}} = 50 \times 12 \times 9/40,000 = 0.135 \text{ sq in.} \]
\[ A_v/2 = 0.0675 \text{ sq in.} << 0.20 \text{ sq in.} \]

Thus, the minimum web reinforcement provided for torsion is more than enough for shear.

(i) Calculate longitudinal torsion reinforcement with Eq. (24)

\[ A_t = 2(A_t/s)(x_1 + y_1)(f_{sv}/f_{y}) \]
\[ = 2(0.0173) (9 + 27) = 1.24 \text{ sq in.} \]

Distribute \( A_t \) around perimeter of stirrups with maximum spacing of 12 in. Eight bars are required.

Use four No. 4 bars and four No. 3 bars.

Area provided = \( 4 \times 0.20 + 4 \times 0.11 = 1.24 \text{ sq in.} \) (ok)

(j) Design reinforcement for ledge

Load on ledge:

DL = 1.4 \times 1.85 = 2.59 \text{ kips per ft}

LL = 1.7 \times 1.20 = 2.04 \text{ kips per ft}

\[ V_u = 4.63 \text{ kips per ft} \]
\[ d = 12 - 2 = 10 \text{ in.} \]

Check for beam action:

\[ v_u = \frac{V_u}{\phi b_w d} = \frac{4630}{0.85 \times 12 \times 10} = 45.5 \text{ psi} < 2\sqrt{f_y} = 141 \text{ psi} \] (ok)

Check for slab action:

\[ v_u = \frac{V_u}{\phi b_o d} = \frac{4 \times 4630}{0.85 \times 21 \times 10} = 104 \text{ psi} < 4\sqrt{f_y} = 282 \text{ psi} \] (ok)

\[ M_u = 4.63 \times 3 = 13.89 \text{ in.-kips per ft} \]

\[ A_s = \frac{M_u}{\phi d f_y} = \frac{13890}{0.9 \times 9.5 \times 40,000} = 0.0405 \text{ sq in. per ft} \]

Even if one-third more than the above steel area is provided, the design is controlled by ACI Code Section 10.5.2.

\[ A_s = 0.002 \times 12 \times 10 = 0.24 \text{ sq in. per ft} \]

Use No. 4 bars at 10 in. on center and one No. 4 bar in each corner.

Check shear friction:

\[ A_{vf} = \frac{V_u}{\phi f_y \mu} = \frac{4630}{0.85 \times 40,000 \times 1.4} = 0.098 \text{ sq in. per ft} < 0.24 \text{ sq in. per ft} \]

The reinforcement details for the L-girder are shown in Fig. 6.
CONCLUSIONS

A procedure for design of torsion in prestressed concrete members has been proposed, which follows the same approach as ACI 318-71 for design of torsion in reinforced concrete members. Comparison with available test results of 132 beams under combined loading as reported in the literature indicates that the proposed procedure is reasonably conservative for rectangular beams and quite conservative for flanged and box beams. The application of the design procedure has been illustrated by a design example.

When more complete research data becomes available, especially for prestressed flanged and box members, the procedure can be further refined and simplified. In the meantime, design tables and curves can be easily prepared to aid the designers in reducing the amount of computation.
